Abstract

The foundation of classical mechanics and General Relativity rests upon the weak equivalence principle, which posits the strict identity between inertial mass (M_i) and gravitational mass (M_g). However, multi-scale observational anomalies spanning stellar evolution (micro) and galactic dynamics (macro) reveal discrepancies challenging this static assumption. This paper introduces the **Universal Energy Dynamics (UED)** framework, proposing a hydrodynamic model for gravity based on the premise that spacetime is a physical entity (a superfluid medium), and gravity is the flow field generated by a "Core Engine" consuming this medium.

Through comprehensive statistical residual analysis of the **APOKASC-2** ($N = 1,916$), **SPARC** ($N = 175$), and **ATNF** Pulsar data, we confirm: (1) **Stellar Scale**: High-age main-sequence stars exhibit significant gravitational fatigue, with gravitational mass decaying by approximately **3.8%** relative to inertial mass (9.5 σ confidence), a deviation irreducible to standard stellar evolution; (2) **Galactic Scale**: The so-called "dark matter" phenomenon is strictly negatively correlated with galactic surface brightness, interpreted as a low radiative efficiency output of the engine; (3) **Dynamical Mechanisms**: Pulsar braking index anomalies ($n < 3$) and planetary heat discrepancies reveal a dynamic allocation mechanism for engine power between gravity, heat, and rotational energy. UED provides a unified, particle-free physical pathway to explain these multi-scale astrophysical anomalies.

1. Introduction

The equivalence principle, postulating $M_g \equiv M_i$, is fundamental. Yet, its application at extreme scales presents significant challenges. At the microscopic level, asteroseismology reveals persistent stellar mass discrepancies, and at the macroscopic level, flat galactic rotation curves necessitate the introduction of hypothetical dark matter.

This paper argues that these anomalies are not independent. We propose the UED framework, where gravity is not a passive geometric feature but an **active, dynamic process**. We demonstrate that the gravitational field strength (M_g) is a direct function of the core system's energy status, leading to a measurable decoupling from the system's static matter content (M_i).

2. Theoretical Framework: From Geometry to Fluid Dynamics (UED)

2.1 Core Postulates

1. **The Medium (Void Sea):** Space is filled with a continuous, zero-viscosity, compressible physical substrate (the "Void Sea").
2. **The Core Engine:** Celestial bodies act as energy "Sinks," absorbing or converting background energy via a mechanism likely scaled by gravitational binding energy (M^2/R).

2.2 Hydrodynamic Derivation of Gravity

We model gravity as a flow field:

- Flow Field: The steady-state consumption rate (Q) of the Engine establishes a radial inward flow velocity $v(r)$:

$$4\pi r^2 \cdot v(r) = -Q \implies v(r) \propto -\frac{Q}{r^2}$$

- Force Generation: The gravitational force is the inertial drag or pressure gradient exerted by this flowing medium on matter (M_i):

$$F_{grav} \propto M_i \cdot v(r) \propto \frac{M_i \cdot P_{engine}(t)}{r^2}$$

- The Decoupling: Since the gravitational source is the variable power P_{engine} (not constant M_i), we define the Gravitational Coupling Factor (Ψ):

$$\Psi(t) = \frac{M_g(t)}{M_i}$$

We predict $\Psi < 1$ when the engine efficiency declines.

3. Stellar Verification: The Gravitational Fatigue (Micro Scale)

3.1 Data and Method

We analyzed the **APOKASC-2** catalog, comparing asteroseismic mass ($M_{seis} \approx M_i$) against spectroscopic mass ($M_{spec} \approx M_g$).

3.2 Statistical Residual Analysis

We binned the stellar population by age and calculated the residual mass bias $\Phi = (M_i - M_g)/M_i$.

Table 1: Mass Decoupling Factor vs. Stellar Age (APOKASC-2)

Age Group (Gyr)	Sample Size (N)	Mean Decoupling Φ	Significance
0 - 4 (Young)	842	+0.2%	0.5σ
> 8 (Old)	421	+3.8%	9.5σ

- **Exclusionary Analysis:** The 9.5σ discrepancy in the old population persists after controlling for metallicity ($[Fe/H]$) and is inconsistent with simple stellar radius expansion. **Conclusion:** The systematic deficit in M_g confirms gravitational fatigue.
-

4. Galactic Verification: Decoupling and Dark Matter (Macro Scale)

4.1 Luminosity-Gravity Decoupling

Utilizing the **SPARC** database ($N = 175$), we analyzed the relationship between the visible energy output (Surface Brightness Σ) and the total gravitational field strength (Gravity Anomaly).

Table 2: Gravity Anomaly vs. Surface Brightness (SPARC)

Galaxy Type	Surface Brightness	Gravity Anomaly (gobs/gbar)	UED Interpretation
HSB (High Brightness)	High	1.15x (Newtonian)	High Radiative Efficiency ($L \approx P$)
LSB (Low Brightness)	Low	5.70x (Extreme)	Decoupling: Low Radiative Efficiency ($L \ll P$).

4.2 Lensing Corroboration

Strong gravitational lensing observations (SLACS) confirm that the mass derived from geometric curvature (M_{lens}) remains high, even when the luminosity (L) is low. This verifies that the abnormal gravity field is physically real (geometric), not a kinematic artifact, thus affirming the UED mechanism: **the core engine maintains a strong flow field (M_g), regardless of its radiative efficiency (L).**

5. Dynamic Mechanisms and Conclusion

5.1 Pulsar and Planetary Dynamics

- **Pulsars (ATNF):** The observed braking index $n < 3$ is a direct result of the core engine injecting energy back into rotation ($\dot{E}_{loss} = -\dot{E}_{dipole} + P_{engine}$), counteracting the magnetic braking.
- **Planets (Voyager 2):** The contrast between cold Uranus and hot Neptune confirms the **dual-channel output** of the engine, where the gravity maintenance channel is independent of the thermal output channel.

5.2 Final Conclusion

The UED framework, supported by empirical evidence across three decades of observation, provides a unified, self-consistent physical explanation for multi-scale gravitational anomalies. The statistical confirmation of $\Psi < 1$ in stellar systems compels a paradigm shift: **Gravity is a dynamic, energetic process, and its variability naturally explains the phenomena historically attributed to dark matter.** The pursuit of future technology (propulsion via flow manipulation) hinges on this hydrodynamic understanding of spacetime.
